Abstract

Bisphenol A (BPA) is a harmful environmental contaminant acting as an endocrine disruptor in animals, but it also affects growth and development in plants. Here, we have elucidated the functional mechanism of root growth inhibition by BPA in *Arabidopsis thaliana* using mutants, reporter lines and a pharmacological approach. In response to 10 ppm BPA, fresh weight and main root length were reduced, while auxin levels increased. BPA inhibited root growth by reducing root cell length in the elongation zone by suppressing *expansin* expression and by decreasing the length of the meristem zone by repressing cell division. The inhibition of cell elongation and cell division was attributed to the enhanced accumulation/redistribution of auxin in the elongation zone and meristem zone in response to BPA. Correspondingly, the expressions of most auxin biosynthesis and transporter genes were enhanced in roots by BPA. Taken together, it is assumed that the endocrine disruptor BPA inhibits primary root growth by inhibiting cell elongation and division through auxin accumulation/redistribution in *Arabidopsis*. This study will contribute to understanding how BPA affects growth and development in plants.

Keywords: auxin, bisphenol A, cell division, cell elongation, ethylene, root

Summary statement:

Endocrine disruptor BPA inhibits primary root growth by reducing cell division in meristem zone and cell elongation in elongation zone through auxin accumulation and distribution.

Introduction

Environmental and agricultural contamination with endocrine disruptors such as bisphenol A (BPA; 2,2-bis(4-hydroxyphenyl)propane) have gained considerable global attention in recent years due to the high potential risk that they pose to the environment, ecosystems and human health (Hunt et al., 2009; Wee and Aris, 2017). Endocrine-disrupting compounds (EDCs) are any chemical compounds that are able to emulate endocrine hormones or act as hormone analogues to interrupt normal hormonal functions. BPA is known as an estrogenic EDC and has been used in the production of various consumer durables, such as polycarbonate, polyacrylate, clear plastic, beverage and food cans and medical equipment (Cooper et al., 2011; Goodson et al., 2002). The annual production of BPA is estimated at 3.7 million tons worldwide (Mihaich et al., 2009). Given that BPA can be released to the soil from different sources, such as wastewater effluents and sewage sludge (Flint et al., 2012; Meesters and Schroder, 2002), plants may face a BPA challenge during their lifespan. Despite many reports regarding the effect of BPA on animals (Canesi and Fabbri, 2015; Flint et al., 2012), relatively little is known about the response of plants to BPA exposure.

According to previous reports, BPA has been found to affect plants in a dose-dependent manner. For example, 1 ppb to 1 ppm BPA positively affects the growth of soybean (*Glycine max*) and the shoot differentiation of carrot (*Daucus carota*) calli (Terouchi et al., 2004). In contrast, BPA was toxic to broad bean (*Vicia faba* L.), tomato (*Solanum lycopersicum* L.), durum wheat (*Triticum durum* Desf.) and lettuce (*Lactuca sativa* L.) at concentrations of 10-50 ppm (Ferrara et al., 2006). A low concentration of BPA (1.5 ppm) enhanced the growth of soybean seedlings, but at higher concentrations (7-50 ppm), it decreased growth, photosynthetic rate and chlorophyll content (Qiu et al., 2013). Exposure of *Arabidopsis thaliana* seedlings to 1-5 μ M BPA (0.23-1.14 ppm) increased root length, lateral root formation and fresh weight, whereas values for these traits were reduced at 10-25 μ M (2.28-5.7 ppm) (Pan et al., 2013).

Higher concentrations of BPA (over 30 μ M) inhibited plant growth by enhancing reactive oxygen species and lipid peroxidation in Arabidopsis (Ali et al., 2017) and soybean (Zhang et al., 2016). It was also reported that approximately 50-100 ppm BPA disrupted microtubule arrays, thereby inhibiting cell division in pea (*Pisum sativum* L.), the gymnosperm *Abies cephalonica*, *Triticum turgidum* (durum wheat) and *Allium cepa* (onion) (Adamakis et al., 2019, 2016, 2013). In addition, 5-10 ppm BPA inhibited pollen tube growth by decreasing the deposition of cell wall components through disrupting Ca^{2+} gradients and actin filaments in *Picea meyeri* (Chang et al., 2015). In mung bean (*Vigna radiata*), BPA treatment caused root and shoot growth retardation at the concentration of 750 ppm and 1000 ppm in soil, respectively (Kim et al., 2018a). Moreover, cucumber (*Cucumis sativus* L.) leaf infiltration with BPA inhibited photosynthesis rate and enhanced reactive oxygen species accumulation (Li et al., 2018a).

The plant hormone auxin has been implicated in various aspects of plant growth and responses to environmental stress, and its accumulation in different parts of the plant mainly relies on its synthesis, conjugation and degradation, and its distribution as affected by polar transport (Grieneisen et al., 2007; Li et al., 2011; Mano and Nemoto, 2012; Petrasek and Friml, 2009; Ruzicka et al., 2007; Wang et al., 2009). During the last decades, the involvement of auxin signaling and transport has been extensively explored in various aspects of root development, such as root cell division and elongation (Ding and Friml, 2010), directional growth of roots (Philosoph-Hadas et al., 2005; Rakusova et al., 2011), and root patterning (Friml et al., 2002; Petersson et al., 2009; Sabatini et al., 1999). The main components of polar auxin transport include the auxin influx carrier AUX1 (AUXIN RESISTANT 1) and the auxin efflux carriers PIN (PIN-FORMED) and ABCB (ATP-binding cassette family B) transporter family proteins (Balzan et al., 2014). In this regard, acropetal auxin transport is mediated mainly by PIN1/3/4/7 from the stele to the meristem, while basipetal transport through lateral root cap and

epidermal cells is regulated by the function of PIN2 and AUX1 (Krecek et al., 2009).

Multiple tryptophan-dependent pathways have been proposed for auxin biosynthesis, including tryptamine (TAM), indole-3-acetaldoxime (IAOx), indole-3-acetamide (IAM), and indole-3-pyruvic acid (IPyA), in which different genes and enzymes such as AMI1 (AMIDASE-LIKE PROTEIN 1), AAO1 (ALDEHYDE OXIDASE 1), YUCCA (YUC), NIT (NITRILASE) and GH3 (PUTATIVE INDOLE-3-ACETIC ACID-AMIDO SYNTHETASE) regulate the synthesis of indole-3-acetic acid (IAA) as an auxin (Mashiguchi et al., 2011; Zhao, 2012).

The involvement of auxin biosynthesis and transport in root growth inhibition under different environmental stress conditions have been reported in several studies. For instance, root length inhibition in response to aluminum is attributed to the altered auxin synthesis via *TAA1* (TRYPTOPHAN AMINOTRANSFERASE OF ARABIDOPSIS 1) and altered distribution through upregulation of *AUX1* and *PIN2* expression (Sun et al., 2010; Yang et al., 2014). Manganese inhibited root elongation by decreasing auxin biosynthesis and auxin transport that was mediated by *PIN4* and *PIN7* (Zhao et al., 2017). Aluminum-treated barley (*Hordeum vulgare*) displayed root growth inhibition with enhanced expression of *DR5* in the meristem, elongation zone, and stele in roots, suggesting that higher auxin may inhibit root growth, probably by decreasing root cell division and elongation (Bai et al., 2017). Copper treatment increased auxin activity (*DR5* expression) in the meristem and elongation zones by reducing *PIN1* expression, leading to reductions in meristem size, cell division activity, and elongation zone size in Arabidopsis (Yuan et al., 2013). Arabidopsis grown on low boron media showed a reduced root meristem size with higher auxin level (low *DII-VENUS* expression) in the stele, which was likely caused by reduced expression of PIN1 (Li et al., 2015a). Nitric oxide negatively regulated auxin transport via downregulation of PIN1, decreasing the primary root growth of Arabidopsis (Fernandez-Marcos et al., 2011). In another study, nitric oxide-mediated

auxin accumulation and signaling were found to be responsible for Cd²⁺-induced root length reduction via reduction of PIN1/3/7 protein level and stabilization of AXR3 and IAA17 proteins (Yuan and Huang, 2016).

The connection between BPA and auxin in root growth inhibition was also suggested. In soybean, root growth and auxin (IAA) increased at 1.5 ppm BPA, while both were reduced at over 3 ppm BPA (Li et al., 2018b; Wang et al., 2015). In addition, the expression level of auxin signaling gene *ACS11* encoding a 1-amino-cyclopropane-1-carboxylate synthase 11 was reduced by over 10 nM BPA in Arabidopsis (Frejd et al., 2016).

Although negative effects of BPA on root growth have been reported in some studies, the molecular mechanisms underlying this inhibition remain poorly understood. Here we elucidated a mechanism that BPA inhibits primary root growth by inhibiting cell elongation and division through auxin accumulation/redistribution in Arabidopsis using gene expressions, mutants, reporter lines and a pharmacological approach because auxin is the most influential hormone in root growth. This study may contribute to understanding how BPA affects plant growth and development.

Materials and methods

Plant materials and growth conditions

All the experiments were performed in *Arabidopsis thaliana* ecotype Columbia (*Col-0*). Transgenic lines used in this study were as follows: *DR5rev::GFP* (ABRC, CS9361), *pPIN1::PIN1-GFP* (ABRC, CS23889), *DII-VENUS* (ABRC, CS799173), *pPIN4::YFP* (NASC, N2106114), *pUPBI::YFP* (NASC, N2106126), *pCYCB1;1::GUS* and *pDR5::GUS* (Dr. Jun Lim, Konkuk Univ) (Kim et al., 2018b; Lee et al., 2012), *pPIN7::GUS*, *pPIN7::PIN7-GUS* (Dr. Eva Benková, Institute of Science and Technology, Austria) (Benkova et al., 2003), *pAUX1::AUX1-YFP* and *pPIN2::PIN2-GFP* (Dr. Klaus Palme, Albert-Ludwigs-University of

Freiburg) (Swarup et al., 2008, 2001). Arabidopsis mutant lines including *pin1* (SALK_047613), *pin2* (SALK_122916C), *pin3-4* (SALK_038609), *pin4-3* (CS9368), *pin7* (SALK_048791C), *abcb1* (SALK_046440), *abcb4* (SALK_072020), *abcb14-2* (SALK_026876C), *abcb15* (SALK_034562C), *abcb19* (SALK_031406), and *aux1* (SALK_020355C) were obtained from the Arabidopsis Biological Resource Center (Ohio State University). All seeds were surface-sterilized and incubated for 3 days at 4 °C for vernalization. The seeds were sown in Petri dishes (90 mm diameter) containing a half-strength MS medium (Murashige and Skoog medium pH=5.7). Then, the plates were placed vertically in a growth chamber under a 16-h light (cool white fluorescent light at 150 $\mu\text{mol m}^{-2} \text{s}^{-1}$)/8-h dark photoperiod and day/night temperatures of 23/21 °C. BPA (Sigma–Aldrich, Korea, Cat# 133027) was dissolved in DMSO to obtain a 100 mM (22,829 mg/L) stock solution and added to the media after autoclaving at the indicated concentrations. All the experiments were performed using 10-day-old seedlings unless otherwise indicated.

Chemical treatments

Stock solutions of 1-naphthylphthalamic acid (NPA) and 1-naphthoxyacetic acid (NOA) were prepared in DMSO, while that of potassium iodide were prepared in water and those of 1-naphthaleneacetic acid (NAA) and indole-3-acetic acid (IAA) were prepared in 1N NaOH, and they were added to the 1/2 MS agar media after autoclaving to make the following concentrations: NPA (Sigma-Aldrich, Korea, Cat# N12507) was prepared at 1 μM , NOA (Thermo Fisher Scientific, Korea, Cat# L01036) at 1 μM , IAA (Sigma-Aldrich, Korea, Cat# I2886) at 100 and 200 nM and NAA (Sigma-Aldrich, Korea, Cat# N0640) at 100 and 200 nM. The plants were treated with these chemicals for 10 days on agar media unless otherwise indicated.

Root examination and measurement

The lengths of the primary root, root meristem, elongation zone and elongation zone cells and the number of root meristem cells were measured using 10-day-old Arabidopsis seedlings grown on 1/2 MS and 1/2 MS supplemented with the indicated concentrations of BPA. Except for the primary root length measurement, seedlings were incubated in 10 $\mu\text{g ml}^{-1}$ propidium iodide for 10 min (Invitrogen, USA) to stain the cell wall. After washing (2-3 times) with distilled water to remove the excess dye, samples were examined with confocal laser scanning microscopy (Leica TCS SP5, Germany). The length and cell number of the root meristem were determined from the quiescent center to the starting point of the elongation zone. For elongation zone cell length, the length of each cell (from start point of elongation zone to the start point of differentiation zone) in the cortex layer was measured, and the average of all cells was indicated. To measure the newly grown root length, 7-day-old seedlings media were exposed to 10 ppm BPA for 24 h and then transferred to the 1/2 MS agar media to grow for two more days. Consequently, the lengths of the newly grown roots for each treatment were measured. All the measurements were performed using ImageJ software (NIH, USA, <http://rsb.info.nih.gov/ij>). At least 30 plants were examined for each experiment, and the average of three independent biological experiments was calculated.

RNA extraction and qRT-PCR analyses

RNA isolation, cDNA synthesis, and qRT-PCR were done as previously reported (Bahmani et al., 2017; Kim et al., 2019). Each qRT-PCR experiment was carried out at least three times with different cDNA sets obtained from three independent biological replicates. The sequence of the primers used for qRT-PCR is listed in Supporting Information Table 1.

Confocal microscopy

5-day-old seedlings of transgenic GFP and/or YFP reporter lines were examined using a

confocal laser scanning microscopy (Leica TCS SP5, Germany). All seedlings were incubated in 10 $\mu\text{g ml}^{-1}$ propidium iodide for 10 min (Invitrogen, USA), except for *pAUX1::AUX1-YFP* and *pUPBI::YFP*, which are mounted in distilled water. The excitation and emission wavelengths were 488 and 505-520 nm for GFP, 514 and 530 nm for YFP, 538 and 617 nm for PI, respectively. Samples were observed at 20 \times magnification with an identical setting for each set of samples to obtain an accurate signal intensity comparison between images. The signal intensity was quantified using ImageJ software (NIH, USA, <http://rsb.info.nih.gov/ij>). For microscopy images, three independent experiments were performed in which at least 10 seedlings were photographed in each treatment, and a representative image is shown.

β -Glucuronidase Assay

Analysis of the β -glucuronidase activity in transgenic plants expressing a GUS reporter was carried out as previously described (Prasinos et al., 2005). In summary, 5-day-old seedlings were immersed in GUS assay solution (50 mM NaPO_4 buffer pH 6.8, 0.5 M EDTA pH 8.0, 0.5 mM potassium ferrocyanide, 0.5 mM potassium ferricyanide, 20% Triton X-100 and 2 mM X-gluc; 5-bromo-4-chloro-3-indolyl-D-glucuronidase) and incubated at 37°C. The GUS staining duration varied for each marker line as follows: 3-8 h for *pDR5::GUS*, 2 h for *pCYCB1;1::GUS*, 30 min for *pPIN7::PIN7-GUS* and 2 h for *pPIN7::GUS*. Images were captured with a microscope (Zeiss Axioplan2). This experiment was repeated three times, and 10 seedlings were examined for each line.

Quantification of bisphenol A

Wild-type (*Col-0*) Arabidopsis seedlings were grown vertically for 2 weeks on a 1/2 MS agar media supplemented with varying concentrations (0 to 10 ppm) of BPA. 1 mL of methanol (Sigma-Aldrich, Korea) was added to ground roots (0.3 mg) and shoots (0.6 mg), and extracted

methanolic supernatants were analyzed. An Acquity UPLC-MS/MS system (Waters, Milford, MA, USA) was used with an electrospray ionization source. The column used for the separation was an Acquity UPLC BEH C18 (1.7 μ m, 2.1 \times 100 mm). The mobile phases consisted of distilled water (solvent A) and methanol (solvent B). The gradient elution was performed at a flow rate of 0.4 mL/min. The following gradient was employed: 0 min, 80:20 (A:B); 4.5 min, 35:65; 5.6 min, 100:0; 7 min 100:0; 7.01 min 80:20; and 9:00 min, 80:20. The multiple reactions monitoring (MRM) was performed in the negative ion mode for mass detection. The target ions used for MRM were m/z 227.1 \rightarrow 212.0 for BPA and m/z 241.3 \rightarrow 223.2 for BPA-d16 (internal standard). The calibration curve was constructed over the concentration range of 10-500 ng/mL. The average of three independent biological experiments was calculated.

Statistical analysis

All data were subjected to an analysis of variance (ANOVA) using SAS software (version 9.1), and comparisons of the means were performed according to Tukey's test at $P \leq 0.05$.

Results

BPA reduces the length of the root elongation zone by repressing cell elongation

Plants were germinated and grown for 14 days on agar media containing a range of concentrations of BPA. The 10 ppm BPA treatment reduced root length by 65% compared to treatments lacking BPA (Figure 1a and c), and there were no visible root hairs at 10 ppm BPA. Correspondingly, BPA accumulation in Arabidopsis increased dramatically at 10 ppm BPA, which explains why Arabidopsis growth was inhibited at 10 ppm BPA (Figure 1b). To understand how the primary root growth was inhibited by BPA, the length of the elongation zone and the cell length were measured. As shown in Figures 1d, e and f, the elongation zone length and the cell length of elongation zone were reduced by approximately 20% in response

to 10-day treatment of 10 ppm BPA. To elucidate the mechanism for the reduction in the elongation zone cell length by BPA, the expressions of *expansin* genes involved in root cell elongation by cell wall loosening (McQueenmason and Cosgrove, 1994) were examined. As shown in Figure 1g, the expression of *EXPA8* (Ma et al., 2013) and *EXPA10* (Che et al., 2016; Kuluev et al., 2012), which are involved in root cell elongation by cell wall loosening, was inhibited by BPA treatment. Among these *expansin* genes, the *AtEXPA10* transcript level was greatly reduced, implying the importance of *AtEXPA10* in root cell elongation. In support of this result, RNAseq data showed a 22-fold reduction of *AtEXPA10* when plants were immersed in 1 ppm BPA solution for 6 h (Table S2).

BPA decreases the length of the root meristem by inhibiting cell division

To examine another candidate for a mechanism by which BPA inhibits the primary root growth, the length and cell number of the meristem zone were measured. As shown in Figure 1f, 2a and b, the meristem length and meristem cell number were reduced by approximately 20% in response to a 10-day treatment of 10 ppm BPA. Next, to examine a mechanism underlying the reduction in meristem cell number, the cell division activity of the meristem was examined using *CYCB1;1::GUS*-expressing Arabidopsis. As shown in Figures 2c, the reduced expression of *CYCB1;1* by BPA indicates decreased cell division activity. In addition, the transcript level and promoter activity of *UPBI* (UPBEAT1), which promotes the transition from cellular proliferation to differentiation between the meristem zone and the elongation zone by regulating reactive oxygen species balance (Tsukagoshi et al., 2010), were enhanced by BPA (Figure 2d and e). This may result in the reduction in root meristem size, which is consistent with the phenotype of *UPBI*-expressing Arabidopsis (Tsukagoshi et al., 2010).

BPA-induced auxin accumulation and redistribution in the root meristem and elongation

zone inhibits cell elongation and division

To elucidate a mechanism for BPA-mediated inhibition of root growth, the auxin level was examined using the *DR5* (auxin-responsive gene) expression in *pDR5::GUS*- (Ulmasov et al., 1997) and *pDR5rev::GFP*-expressing (Benkova et al., 2003) transgenic Arabidopsis. As shown in Figures 3a, *DR5-GUS* expression was enhanced at the meristem and stele by 1 ppm BPA and this expanded to the elongation zone at 10 ppm BPA, indicating higher accumulation of auxin in these regions (meristem zone, elongation zone and stele) in response to BPA. *DR5-GFP* expression was also increased in the meristem zone and stele by 10 ppm BPA (Figure 3c). In addition, *DR5-GUS* expression was fully enhanced within 24 h by 10 ppm BPA in the meristem zone, elongation zone and stele (Figure 3b). Furthermore, *DII-VENUS*, the auxin-signaling sensor (Brunoud et al., 2012), which is degraded by auxin, displayed a reduced expression in response to BPA, indicating higher accumulation of auxin by BPA (Figure 3d). These data suggest that in response to BPA, auxin was transported downward to the meristem zone via the stele and then was transported upward to the elongation zone; therefore, a higher level of auxin may repress cell division and cell elongation in the meristem zone and elongation zone, respectively. In addition, auxin over-accumulation may reduce root meristem enlargement (Li et al., 2015b).

To examine whether the enhanced auxin actually inhibits cell elongation and division in roots, *Col-0* Arabidopsis was germinated and grown for 10 days on 1/2 MS agar plates with and without 100 nM and 200 nM IAA and NAA. As shown in Figures 4a-d, primary root growth and expressions of *EXPA8*, *EXPA10* and *CYCBI;1* were reduced by IAA and NAA, suggesting that BPA-induced auxin accumulation in the elongation zone and meristem zone inhibits root growth by reducing cell elongation and division.

Auxin biosynthesis is enhanced in response to BPA

To understand how the auxin level was increased in the meristem and stele, the expression levels of the auxin biosynthesis genes *AtAAOI* (ALDEHYDE OXIDASE 1, AT5G20960), *AtAMII* (AMIDASE 1, AT1G08980), *AtNIT1* (NITRILASE 1, AT3G44310), *AtYUCCA1* (YUC1, AT4G32540), and *AtYUCCA5* (YUC5, AT5G43890) were measured using qRT-PCR. As shown in Supporting Information Figure 1 (Figure S1), all genes involved in auxin biosynthesis except *NIT1* displayed enhanced expressions in response to BPA, suggesting that BPA increased the auxin level in roots by enhancing the biosynthesis of auxin in Arabidopsis. Based on the enhanced expressions in *AAOI* and *AMII* but not in *NIT1* by BPA, it appears that BPA promotes the auxin synthetic pathway involving IPyA (indole-3-pyruvic acid) and IAM (indole-3-acetamide) rather than IAN (indole-3-acetonitrile).

BPA modulates the auxin distribution in roots by regulating the expressions of auxin transporters

To examine how auxin transporters participate in BPA-induced auxin distribution, the expression levels of the auxin transporter genes *AtABCB1* (ATP-BINDING CASSETTE B1, AT2G36910), *AtABCB4* (AT2G47000), *AtABCB14* (AT1G28010), *AtABCB15* (AT3G28345), *AtABCB19* (AT3G28860), *AtPIN1* (PIN-FORMED 1, AT1G73590), *AtPIN2* (AT5G57090), *AtPIN3* (AT1G70940), *AtPIN4* (AT2G01420), *AtPIN7* (AT1G23080) and *AtAUX1* (AUXIN RESISTANT 1, AT2G38120) were examined using qRT-PCR. As shown in Supporting Information Figure 2 (Figure S2), the transcript levels of the auxin efflux transporters *ABCBs* (ATP-BINDING CASSETTE B) and *PINs* (PIN-FORMED), except *PIN3*, were increased by BPA, while that of the auxin influx transporter *AUX1* was reduced in response to BPA. In addition, the protein expression levels of auxin transporters were examined (Figure 5). *pPIN1::PIN1-GFP* Arabidopsis showed that PIN1 protein was mainly expressed in the stele (Friml et al., 2002) and was enhanced by BPA (Figure 5a). While the transcript level of PIN2

was enhanced by BPA (Figure S2), *pPIN2::PIN2-GFP* Arabidopsis displayed reduced expression of PIN2 protein (Figure 5b), suggesting that the protein level does not match the transcript content for PIN2. *pPIN4::YFP*-Arabidopsis showed that *PIN4* was mainly expressed in the root tip (quiescent center and columella) and stele (Friml et al., 2002; Marques-Bueno et al., 2016), and the expression was enhanced but not expanded to other areas by BPA (Figure 5c). *pPIN7::PIN7-GUS* Arabidopsis indicated that PIN7 protein was expressed in the root tip (columella) and stele (Vieten et al., 2005) (Figure 5d). Interestingly, PIN7 protein was not increased by BPA, whereas the *PIN7* transcript was enhanced by BPA (Figure 5d, e and S2), suggesting that PIN7 is not involved in auxin redistribution induced by BPA. In addition, *pAUX1::AUX1::YFP*-expressing Arabidopsis showed that BPA reduced the expression of the auxin influx transporter AUX1, which was localized in the epidermis, stele and tip (Figure 5f).

To confirm the involvement of auxin transporter-mediated auxin redistribution in BPA-induced root growth inhibition, root growth in response to BPA in auxin transporter mutants was examined. As shown in Figure 5g, most auxin transporter mutants examined, except *pin3* and *pin7*, displayed less reduction in root growth inhibition in response to BPA compared to the control *Col-0*. Since the *PIN3* transcript level (Figure S2) and PIN7 protein level (Figure 5d) were not significantly increased by BPA, *pin3* and *pin7* did not show any difference from the control in root growth inhibition, suggesting that PIN3 and PIN7 are not involved in BPA-induced auxin redistribution. Therefore, auxin is redistributed in response to BPA via the auxin transporters PIN1, PIN2, PIN4, AUX1, and ABCBs in response to BPA.

To confirm the participation of auxin redistribution in BPA-induced root growth inhibition, NPA (auxin efflux inhibitor) and NOA (auxin influx inhibitor) were applied. As shown in Figure 6a, both NPA and NOA partially restored root growth inhibition incurred by BPA, indicating the partial engagement of auxin transporter-mediated auxin redistribution in BPA-inhibited root growth. In support of this, treatment with NPA or NOA decreased BPA-

induced *DR5-GUS* expression/auxin accumulation in meristem zone, elongation zone and the stele (Figure 6b). Interestingly, NOA was more effective than NPA in reducing auxin accumulation. In addition, the NPA treatment partially rescued the BPA-inhibited expression of *CYCB1;1*, which was not the case for NOA, suggesting the participation of auxin efflux but not influx in cell division inhibition induced by BPA (Figure 6c).

Discussion

In this study, for the first time, we have shown that BPA inhibits primary root growth by inhibiting cell division and elongation through auxin accumulation in the root meristem zone, transition zone, and elongation zone.

In response to 10 ppm BPA, the length of the meristem zone was reduced leading to a decrease in the main root length. This result may be caused by BPA-induced accumulation of auxin in the meristem. However, it has been reported that auxin is positively involved in stem cell niche and cell division activity in the meristem (Sabatini et al., 1999; Takatsuka and Umeda, 2014). Therefore, the decreased auxin accumulation in root tips is responsible for the lower cell division activity in the root meristem, thereby inhibiting root growth (Fernandez-Marcos et al., 2011; Yuan and Huang, 2016; Zhao et al., 2017). By contrast, several reports showed that higher auxin accumulation is involved in inhibiting cell division, thereby in reducing the meristem size. Treatment with the cytokinin 6-benzyladenine reduced the meristem size and root length probably by increasing auxin level (*DR5* expression) in the stele, meristem zone and elongation zone via decreasing *PIN1*, 2, and 3 expression and by enhancing the *PIN7* level in Arabidopsis (Ruzicka et al., 2009). Alkaline stress decreased cell division activity by enhancing ethylene- and *AUX1*-mediated auxin accumulation in the root meristem in Arabidopsis (Li et al., 2015b). Benzoic acid reduced the size of the meristem and elongation zone by ethylene-mediated auxin accumulation in root tips (meristem and elongation zone) via auxin biosynthesis, *AUX1* and

PIN2 in Arabidopsis (Zhang et al., 2018a). Based on these findings, our results suggest that BPA reduces meristem size and thus root length by inhibiting cell division through accumulating auxin in the meristem. However, it is also possible that BPA directly inhibits cell division since BPA disrupts microtubule arrays in *Pisum sativa*, the gymnosperm *Abies cephalonica*, *Triticum turgidum* (durum wheat), and *Allium cepa* (onion) (Adamakis et al., 2019, 2016, 2013).

Furthermore, the reduced cell length of the elongation zone by BPA might be ascribed to decreased expression of *EXPA8* and *10*. Additionally, the BPA-induced accumulation of auxin in the transition zone and elongation zone (Figure 3a) may be responsible for the decreased cell elongation in the elongation zone, since auxin was negatively involved in cell elongation in the elongation zone when plants were challenged by benzoic acid (Zhang et al., 2018a), boron deficiency (Camacho-Cristobal et al., 2015) cell wall damage (Tsang et al., 2011), ethylene (Ruzicka et al., 2007; Swarup et al., 2007), and tungsten (Adamakis et al., 2014). Furthermore, the expression of *EXPA8* and *EXPA10* was reduced by IAA and NAA (Figure 4b and c). Combining these results, it seems that the cell elongation repression by BPA is ascribed to the reduced expression of *EXPA8* and *10* by higher accumulation of auxin in the elongation zone. However, in contrast to our results, several studies have shown a positive relationship between auxin and *expansin* expression. IAA-treated Arabidopsis seedlings showed higher expression levels of *EXPA1*, *EXPA4*, and *EXLA3* (Nemhauser et al., 2006). Moreover, several *expansin* and related genes, including *EXPA1*, *EXPA7*, *EXPA10*, *EXPA12*, *EXPA18*, *EXLA1*, *EXLA2*, and *EXLA3*, were upregulated in response to picloram (4-amino-3,5,6-trichloropicolinic acid; a synthetic auxin) in the elongating hypocotyls of Arabidopsis seedlings (Chapman et al., 2012). In *CYP71Z2*-overexpressing rice, which exhibited a lower level of IAA and higher resistance to bacterial blight, the expression levels of six *expansin* genes, including *OsEXPA1*, *OsEXPA5*, *OsEXPA10*, *OsEXPB3*, *OsEXPB4* and *OsEXPB7*, were downregulated

(Li et al., 2015c). In another study on rice, pathogen-induced IAA production positively regulates the transcript levels of *expansin* genes and enhanced cell wall flexibility (Cosgrove, 1993; Ding et al., 2008). In contrast, it was also reported that auxin is positively involved in cell elongation in the elongation zone; a lower level of auxin in the elongation zone due to aluminum-induced auxin accumulation in the transition zone is responsible for reduced cell elongation in *Arabidopsis* (Liu et al., 2016; Yang et al., 2014), and aluminum-treated maize displayed a decrease in auxin level in the transition zone and elongation zone, resulting in root growth inhibition (Zhang et al., 2018b), which supports the report of Kollmeier et al. (2000) in which IAA treatment to the elongation zone reduced root growth inhibition induced by aluminum application to the transition zone.

The higher accumulation of auxin in the root meristem is attributed to the enhanced *PIN1* and *PIN4* levels and to reduced *PIN2* and *AUX1* expression (Figure 5). Since *PIN1/4* are involved in the acropetal downward transport of auxin to the meristem via the stele (Blilou et al., 2005; Wabnick et al., 2011), the enhanced expression of *PIN1/4* resulted in the higher level of auxin in the meristem. Consistent with this result, BPA increased the transcript levels of auxin efflux transporters *ABCBs* (*AtABCB1*, *AtABCB4*, *AtABCB14*, *AtABCB15* and *AtABCB19*), and *PINs* (*AtPIN1*, *AtPIN2*, *AtPIN4* and *AtPIN7*), while that of the auxin influx transporter *AUX1* was reduced in response to BPA (Figure S2).

PIN1 is positively involved in auxin accumulation in the root meristem/tip (Fernandez-Marcos et al., 2011; Ruzicka et al., 2007; Yuan and Huang, 2016; Yuan et al., 2013). In contrast, the auxin level increased at the stele with reduced *PIN1* expression in response to benzyladenine (Ruzicka et al., 2009), copper (Yuan et al., 2013), and low boron (Li et al., 2015a). In addition, *PIN3* (Yuan and Huang, 2016), *PIN4* (Zhao et al., 2017) and *PIN7* (Ruzicka et al., 2009; Yuan and Huang, 2016; Zhao et al., 2017) are engaged in auxin accumulation in roots. Interestingly, *PIN2* and *AUX1*, which participate in the basipetal shootward transport of auxin, are positively

involved in auxin accumulation in the root meristem zone and elongation zone (Camacho-Cristobal et al., 2015; Ruzicka et al., 2007; Swarup et al., 2007; Zhang et al., 2018a). Therefore, the BPA-inhibited expression of *PIN2* and *AUX1* (Figure 5) suggests that sufficient auxin is transported to the elongation zone, even with lower levels of *PIN2* and *AUX1*. Similar results were also reported in root growth inhibition by boron deficiency (Camacho-Cristobal et al., 2015).

In addition, the enhanced expression of *ABCB1/4/19* by BPA (Figure S2) likely enables higher amounts of auxin to translocate upward from the root tip to the elongation zone. Basipetal auxin transport in the root tip of *Arabidopsis* is mediated by the concerted function of *PIN2* (Friml et al., 2003; Muller et al., 1998), *ABCB1* (Geisler et al., 2005), *ABCB4* (Terasaka et al., 2005; Wu et al., 2007), and *AUX1* (Swarup et al., 2001) towards the root elongation zone. The *abcb1* and *abcb4* mutants exhibited reduced basipetal auxin transport (Geisler et al., 2005; Lewis et al., 2007). However, the functional redundancy of *AtABCB1* and *ABCB19* cannot be excluded (Bouchard et al., 2006; Geisler et al., 2003).

In conclusion, BPA inhibits primary root growth by repressing cell division in the meristem zone and cell elongation in the elongation zone through auxin accumulation/redistribution in the meristem zone and elongation zone in *Arabidopsis*.

Figure legends

FIGURE 1 BPA inhibits primary root growth by reducing the length of the elongation zone and *expansin* expression in Arabidopsis. (a) Longitudinal views of the wild-type (*Col-0*) Arabidopsis seedlings grown for 2 weeks on a 1/2 MS agar media supplemented with varying concentrations (0 to 10 ppm) of BPA. (b) Accumulation levels of BPA in Arabidopsis in (a). (c) Primary root length, (d) the length of the elongation zone, (e) the cell length of the elongation zone, and (f) the longitudinal views of the Arabidopsis seedlings grown for 10 days on the control (1/2 MS) and agar media supplemented with 10 ppm BPA; bar=400 μ M. (g) Transcript levels of *AtEXPA8* and *AtEXPA10* determined by qRT-PCR in roots of Arabidopsis seedlings. Data indicate the mean \pm standard error (SE) of three independent experiments. Different letters above the columns represent statistical differences between treatments according to Tukey's multiple comparison test ($p \leq 0.05$). For microscopy images, three independent experiments were performed in which at least 10 seedlings were photographed in each treatment, and a representative image has been displayed.

FIGURE 2 BPA inhibits primary root growth by reducing the length of the meristem zone and *CYCB1;1* expression in Arabidopsis. (a) The length of the meristem zone. (b) The number of meristem cell. (c) Cell division activity in *CYCB1;1::GUS* seedlings; bar=100 μ M. (d, e) Transcript level of *AtUPB1* in roots of Arabidopsis seedlings, and confocal images showing the YFP fluorescence in roots of *pUPB1:YFP* seedlings (bar=100 μ M). Data indicate the mean \pm SE (n=3). Different letters above the columns represent statistical differences between treatments (Tukey's test, $p \leq 0.05$).

FIGURE 3 Enhancement of auxin accumulation/distribution by BPA in Arabidopsis. (a) Prolonged (8 h) GUS staining in roots of *DR5::GUS* seedlings treated with 0 (1/2 MS control),

100 ppb, 1 ppm, and 10 ppm BPA; bar=100 μ M. (b) GUS staining in roots of 5-day-old DR5::GUS seedlings treated with 10 ppm BPA for 0, 6, 12 and 24 h; bar=100 μ M. (c) Confocal images of *DR5rev::GFP* seedlings; bar=100 μ M. (d) Confocal images of *DII-VENUS* seedlings; bar=100 μ M.

FIGURE 4 Reductions of root growth, *expansin* expression and cell division activity by auxin in Arabidopsis. (a) Primary root lengths of the Arabidopsis seedlings treated without (1/2 MS) and with IAA (100 and 200 nM) and NAA (100 and 200 nM) for 10 days. (b, c) Transcript levels of *AtEXPA8* and *AtEXPA10* determined by qRT-PCR in the roots of Arabidopsis seedlings grown and treated as in (a). (d) GUS expression in roots of *CYCBI;1::GUS* seedlings grown in the presence and absence of 200 nM IAA or NAA; bar=100 μ M. Data indicate the mean \pm SE (n=3). Different letters above the columns represent statistical differences between treatments (Tukey's test, $p \leq 0.05$).

FIGURE 5 Modulation of auxin transporter expressions by BPA and root growth inhibitions in auxin transporter mutants. Confocal images of *pPIN1::PIN1-GFP* (a), *pPIN2::PIN2-GFP* (b) and *pPIN4::YFP* (c), and GUS staining of *pPIN7::PIN7-GUS* (d) and *pPIN7::GUS* (e), and confocal image of *pAUX1::AUX1-YFP* (f) seedlings grown for 5 days on 1/2 MS agar media supplemented without (left) and with 10 ppm BPA (right); bar=100 μ M. (g) BPA-induced root growth inhibition in wild-type (*Col-0*) and various auxin transporter mutants. Seven-day-old *Col-0* and auxin transporter mutants grown on 1/2 MS agar media were exposed to 10 ppm BPA for 24 h, and the lengths of newly grown roots were measured after growth for an additional 2 days on 1/2 MS media. For each line, the value of root growth in the control condition (1/2 MS) was set as 100%, and the relative value of BPA-treated seedlings was calculated. Data indicate the mean \pm SE (n=3), and each includes >30 seedlings. Asterisks represent significant

differences between lines in the presence of BPA ($P \leq 0.05$). n.s; no significant difference.

FIGURE 6 Treatment with auxin efflux inhibitor (NPA) and influx inhibitor (NOA) restores BPA-induced root growth inhibition, *DR5* induction and *CYCB1;1* repression. (a) Primary root length of wild-type (*Col-0*) Arabidopsis grown for 10 days on media supplemented without and with BPA (10 ppm) in the presence or absence of NPA (1 μ M) and NOA (1 μ M). (b) GUS staining in roots of *DR5::GUS* seedlings treated without and with BPA (10 ppm) in the presence or absence of NPA (1 μ M) and NOA (1 μ M) for 5 days; bar=100 μ M. Graph (right) shows the quantification of the GUS staining. (c) GUS expression in roots of *CYCB1;1::GUS* seedlings grown and treated as in (b). Graph (right) is the quantification of the GUS staining. Data indicate the mean \pm SE (n=3). Different letters above the columns represent statistical differences between treatments (Tukey's test, $p \leq 0.05$).
